

UNIX Commands & Pair Programming

Objectives

- Able to make use of many common UNIX/Linux commands
- Learn an editor: VIM/EMACS
- Experience pair programming (optional for this lab)
- Learn Unix Commands

Lab 1 Exercise – UNIX

Step 1: - Find a partner

Buddy-up to help get through the answers faster and also experience pair programming. You will need to sit next to each other.

If there ends up being an extra person, then you can make one group of 3.

Step 2: - VM

Ensure you have the latest Virtual Machine from the CS department:

<https://foundation.cs.colorado.edu/> You should have VirtualBox, VM, Dropbox.

Open your VM and open a terminal window so we can play with UNIX!

Step 3: - Text Editors

Unix systems feature a lot of different text editors, such as pico, emacs and vi (pronounced as “vee-i” also known as vim. We do not require a specific text editor in this class, so use whichever program suits your working style the best. However, you should experience each once so you are somewhat familiar with them, and you will need to be very familiar with either vim or emacs.

To get you started, you can learn about these programs by accessing their on-line help and/or tutorials.

Program	Help	Tutorial
emacs	Launch emacs , type Ctrl-h	Type <i>emacs</i> , then Ctrl-h t
vim	Launch vim , type :help	Type vimtutor
pico	Launch pico , type Ctrl-G	N/A

Of course, you can always get more information on the Web by performing a search in your favorite search engine using e.g., a phrase like “pico tutorial”.

The TA will guide you through a brief introduction to vi. However, there is no restriction on using only vim for this course.

For the rest of this lab, use either vim or emacs to record your answers!

Step 4: - UNIX Commands

UNIX commands enable you to do some powerful programming in very few characters. You can either enter the commands at the terminal, or put them in a file and run them as a script. Nearly all Unix commands follow the same basic structure in how they are entered.

`command -option argument --more-options`

Using either vim or emacs, create a file with the following information:

1. What do the following commands do?

Command	Does what?
date	
ls -ltr	
cd ..	
pwd	
who	
whoami	
man man	
Env	

2. How would you do the following? (Work with your buddy! Search the Internet!)

Some useful commands you may need: `grep`, `cd`, `mkdir`, `rm`, `find`, `head`, `tail`, `cp`, `zip`, `unzip`, `rmdir`, `cat`, `sort`, `uniq`, `less`, `touch`.

Command	Goal
	Make a directory named <code>cs3308</code> and move into that directory.
	Rename your directory <code>cs3308</code> to <code>csci3308</code> .
	Create a new file <code>lab1.txt</code> and make a copy of that file named <code>lab1_copy.txt</code> .
	Delete the copy of your file – <code>lab1_copy.txt</code> (Careful!)
	Make a directory named <code>tmp</code> . Then delete that directory.
	View the contents of a file. 2nd way to view the contents of a file.
	View just the beginning of a file.
	View just the end of a file.

	List all files (filenames) that contain the word “the” in the file content.
	List full path to all files named “lab1.txt” or any other file which you have on your machine.
	Zip the contents in your directory into a file named dir.zip. Unzip your zipped file dir.zip into a new directory named tmp. Tar the contents in your directory into a file named dir.tar. Untar your zipped file dir.tar into a new directory named tmp
	Modify a file’s last modified timestamp to now. This also creates a new file if it doesn’t currently exist.

Step5: - Fancy UNIX commands

For the next set of questions, use the following file: (Create a new file and copy the following content)

```
root:x:0:0:root:/root:/bin/bash
daemon:x:2:2:daemon:/sbin:/sbin/nologin
bin:x:1:1:bin:/bin:/sbin/nologin
harpo:x:12502:1000:Harpo Marx:/home/harpo:/bin/csh
chico:x:12501:1000:Chico Marx:/home/chico:/bin/bash
zeppo:x:12505:1000:Zeppo Marx:/home/zeppo:/bin/zsh
groucho:x:12503:2000:Grouch Marx:/home/groucho:/bin/sh
gummo:x:12504:3000:Gummo Marx:/home/gummo:/usr/local/bin/ksh
```

Source: <http://www.cyberciti.biz/faq/understanding-etcpasswd-file-format/>

Understanding fields in /etc/passwd

The /etc/passwd file contains one entry per line for each user (or user account) of the system. All fields are separated by a colon (:) symbol. Total seven fields as follows.

Generally, passwd file entry looks as follows:

oracle:x:1021:1020:Oracle user:/data/network/oracle:/bin/bash

↓ ↓ ↓ ↓ ↓ ↓ ↓

1 2 3 4 5 6 7

(/etc/passwd file format)

1. **Username:** It is used when user logs in. It should be between 1 and 32 characters in length.
2. **Password:** An x character indicates that encrypted password is stored in /etc/shadow file
3. **User ID (UID):** Each user must be assigned a user ID (UID). UID 0 (zero) is reserved for root and UIDs 1- 99 are reserved for other predefined accounts. Further UID 100-999 are reserved by system for administrative and system accounts/groups.
4. **Group ID (GID):** The primary group ID (stored in /etc/group file)

5. **User ID Info:** The comment field. It allows you to add extra information about the users such as user's full name, phone number etc., This field use by finger command.
6. **Home directory:** The absolute path to the directory the user will be in when they log in. If this directory does not exist, then users' directory becomes /
7. **Command/shell:** The absolute path of a command or shell (/bin/bash). Typically, this is a shell. Please note that it does not have to be a shell.

3. Using the above mentioned file as input, please figure out the commands that do the following tasks:

Command	Does what?
	Sort the file based on the username (first field)
	Sort the file based on the UID. Since it is a number, be sure to specify that it is a number so it sorts the numbers correctly.
	Sort first based on GID, then on UID.
	Show all the lines in the file with the word 'Marx' in it.
	Get the number of lines in the file (from a Unix command)
	Use your command for the previous question and now redirect the output to a file named tmp.
	<p>Now write your answer (command) to find the number of lines question to a separate file with an extension of .sh for example the file name can be getUniqueGID.sh. Try to run your program.</p> <p>You should get command not found. Try to run ./getUniqueGID.sh. You should get Permission denied. Change the permissions on the file to allow users to execute the file. Now, which method runs your program? And why doesn't the other one execute? And what is a second way to have changed the permissions? And do you know a third way?</p>
